

## 10. What are global attributes. List any 5 global attributes.

Global attributes are attributes that can be used with all HTML elements. They are not specific to any particular element. Global attributes are used to provide additional information about an element, such as its language, its style, or its accessibility.

Here are some of the most common global attributes:

- **accesskey** - Specifies a keyboard shortcut that can be used to select or activate the element.
- **class** - Specifies a class name for the element. Classes can be used to style the element or to group it with other elements.
- **dir** - Specifies the directionality of the element's text. The possible values are "ltr" (left to right) and "rtl" (right to left).
- **id** - Specifies a unique ID for the element. IDs can be used with CSS and JavaScript.
- **lang** - Specifies the language of the element's content.
- **style** - Specifies an inline style for the element.
- 

Global attributes can be used to make HTML documents more accessible, more efficient, and more stylish.
